Regulation Market Discussion: Basic Concepts

RPSTF February 7, 2012 Howard J. Haas

Regulation Historically Provided by "Slow" Resources

- Regulation has historically been provided by traditional generation resources (Slow) following a regulation signal (Reg A).
- PJM has always been able to meet its regulation performance objectives using Slow resources following the regulation signal (Reg A).
- KEMA study indicates that regulation can be achieved through a combination of Slow resources and fast response regulation sources (Fast).

Regulation Can Be Provided by a Combination of Resources: Fast and Slow

- Premise is that a combination of fast and slow would be more efficient at providing regulation:
 - Can use fewer resources to achieve the same amount of regulation
 - Lower cost to achieve the same amount of regulation
- For this premise to be true, there has to be a defined relationship between the use of fast and slow resources, for any level of regulation provided.

Defining the Relationship Between Fast and Slow Resources

- For this premise to be true, there has to be a defined relationship between the use of fast and slow resources, for any level of regulation provided.
 - The rate of substitution
 - KEMA Study indicates that the rate of substitution between Fast and Slow is not constant
 - They are not perfect substitutes
 - **Cannot completely replace Slow with Fast**
 - o Can replace Fast with Slow
 - There may be a better solution than using all Slow

Regulation Production Function

- What has been described is a production function for regulation
 - Production function describes the relationship between inputs in producing a product (regulation)
 - Given the prices for the inputs, production function permits finding the least cost (most efficient) combination of inputs needed to provide a given level of product.
 - The most efficient combination of inputs depends on:
 - price of the inputs
 - the rate of substitution between the inputs

Defining the Optimal Mix: Fast and Slow

- What has been described is a production function for regulation:
 - R = f(X,Y)
 - X= Units of Slow , Y = Units of Fast
- Cost of any combination of X and Y:
 - Cost(X,Y)= (Price_x * Quantity_x) + (Price_y * Quantity_y)
- Objective is to minimize the cost for a given amount of regulation (R)
 - The amount of regulation means meeting the **CPS/BAAL** requirements

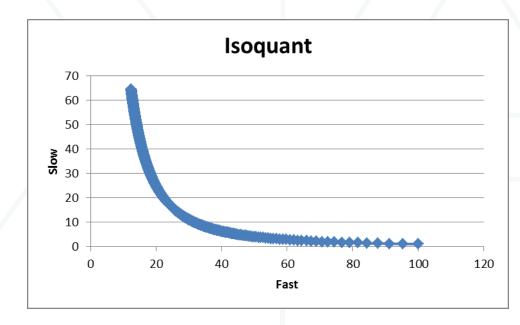

Production Function and Rate of Substitution

Two Input Markets: Fast and Slow

- Two input products (fast and slow)
- Two markets (fast and slow)
- Two sets of prices and quantities
- Optimal market solution requires understanding the engineering relationship (tradeoffs and mutual benefits)
- Objective to minimize total cost to provide the service given markets for each input
