

# PJM Manual 15:

Cost Development Guidelines

Revision: 29

Effective Date: May 15, 2017

Prepared by  
Cost Development Subcommittee

PJM © 2017

## Section 12: Energy Market Opportunity Cost and Non-Regulatory Opportunity Cost Guidelines

### 12.7 IMM Opportunity Cost Calculator

#### 12.7.1 Calculation Method

The Opportunity Cost Calculator selects the hours of operation that will maximize the generator's energy market revenue net of the generator's short run marginal cost of producing energy, subject to the unit specific environmental or operational limits. The duration and structure (i.e. rolling compliance periods or a single compliance period) of the optimization period will be as specified in an environmental permit for environmental limitations, or as specified by the original equipment manufacturer or insurance carrier for physical equipment limitations. In the case of a fuel supply limitation, the duration of the optimization period must be approved by PJM and the MMU.

Inputs into the Opportunity Cost Calculator will include unit specific forward LMPs based on futures prices, unit specific forward fuel prices based on futures or contract prices, and unit specific operating parameters.

The opportunity cost is the shadow price corresponding to the binding environmental or operational limit. The shadow price is defined as the marginal decrease in the net revenue due to a one hour equivalent decrease in the binding environmental or operational limit. Opportunity cost therefore is the marginal value of the foregone opportunity to earn higher profits for an environmentally or operationally constrained unit.

Energy Market Opportunity Costs and Non-Regulatory Opportunity Costs are a distinct component of the cost-based offer. As is the case with any computation of the cost-based offer in Manual 15, Market Sellers may elect to enter their cost-based offer at a value less than the computed cost-based offer. However, they may not exceed the computed value.

#### 12.7.2 Forward LMP

Unit specific hourly forward LMPs are based on off peak and on peak future contracts for PJM Western Hub or any neighboring frequently traded PJM hub with expiration dates during the optimization period. The futures contract price will be multiplied by a basis differential and an hourly volatility scalar. The basis differential accounts for the price difference between the location of the forward contract delivery point (PJM Western Hub) and the relevant generator bus. The hourly volatility scalar incorporates hourly volatility into the forward LMP.

Three different historical time periods will be identified and mapped on an hourly basis to the optimization period. Historical on peak hours will be mapped to on peak hours in the optimization period, and historical off peak hours will be mapped to off peak hours in the optimization with adjustments made to ensure historical holiday and weekend days are mapped to holiday and weekend days during the optimization period. For example, if the calculation date is January 25, 2019 and the optimization period is one year into the future, then three different historical time periods, each consisting of 8,760 hours from the three year period preceding January 25, 2019, will be identified. Each of the three historical time periods will be mapped to the 8,760 hours in the optimization period such that on peak hours are mapped to on peak hours, off peak hours are mapped to off peak hours, holidays are mapped to holidays, and weekend days are mapped to weekend days.

Three on peak and three off peak basis differentials will be computed for each futures contract.

used in the calculation of the forward LMPs using the three historical time period mappings. The on peak basis differential will be calculated as the average of the ratio of the hourly bus LMP to the hourly Western Hub LMP, with the average being taken over all on peak hours during the identified historical time period where the month corresponds to the futures contract month of expiry. The off peak basis differential will be calculated as the average of the ratio of the hourly bus LMP to the hourly Western Hub LMP, with the average being taken over all off peak hours during the identified historical time period where the month corresponds to the futures contract month of expiry.

Three hourly volatility scalars will be computed for each hour during the optimization period based on the three different historical time period mappings. For an on peak hour in the optimization period, the hourly volatility scalar will be calculated as the ratio of the historical bus LMP to the average historical bus LMP, with the average being taken over all on peak hours during the identified historical time period where the month corresponds to the month of the on peak hour in the optimization period. For an off peak hour in the optimization period, the hourly volatility scalar will be calculated as the ratio of the historical bus LMP to the average historical bus LMP, with the average being taken over all off peak hours during the identified historical time period where the month corresponds to the month of the off peak hour in the optimization period.

### **12.7.3 Forward Delivered Fuel Price**

Unit specific daily forward delivered fuel prices are based on traded forward fuel prices from a published source or prior contractually agreed prices. A fuel delivery charge is added to the monthly forward fuel prices to obtain delivered fuel prices, and the delivered fuel prices are multiplied by daily volatility scalars to obtain a daily forward delivered fuel price for the generator. For generators procuring fuel at a contractual rate, a volatility scalar is not applied and a constant contracted price is used. Three volatility scalars are computed for each day in the optimization period based on the three different historical time period mappings. The daily volatility scalar is computed as the ratio of the historical daily delivered fuel price to the average monthly historical delivered fuel price.

### **12.7.4 Operating Cost**

The hourly operating cost (\$ per MWh) is the short run marginal cost of generating energy. Inputs into the calculation of the hourly operating cost consist of the forward delivered fuel price, the generator's heat rate data, emission rate data, and VOM cost available in the Member Information Reporting Application (MIRA), and emission futures prices. The calculation of hourly operating cost is consistent with the calculation of cost based offers specified in PJM Manual 15.

The hourly operating cost or operating parameters may be adjusted in cases where the unit's historical offer behavior deviates from the short run marginal cost or the commitment and dispatch of the generator has historically differed from expected economic outcomes due to actions taken by the Transmission Provider or other factors outside the control of the Market Participant. The application, and the magnitude and direction, of any adjustment is dependent upon an expectation that the offer behavior or conditions that cause the noneconomic commitment and dispatch of the unit will persist into the optimization period and that the unit will be subject to mitigation.

### **12.7.5 Emissions and Operating History**

Up to date emissions totals, hours of operations, or number of starts are critical inputs into the Opportunity Cost Calculator. Market Participants are required to update the values in MIRA on a weekly basis. Opportunity cost adders will not be calculated for generators that do not have up

to date emissions totals, hours of operations, or number of starts, and Market Participants will not be allowed to include an opportunity cost adder in the generator's cost based offer.

### **12.7.6 Opportunity Cost Adder**

For each of the three sets of forward LMPs and forward delivered fuel prices, the Opportunity Cost Calculator selects the hours of operation that maximize the generator's energy market revenue net of the generator's short run marginal cost of producing energy, subject to the unit specific environmental or operational limits. The duration and structure (i.e. rolling compliance periods or a single compliance period) of the optimization period will be as specified in an environmental permit for environmental limitations, as specified by the original equipment manufacturer or insurance carrier for physical equipment limitations, or as agreed upon by the Market Participant, PJM and the MMU in cases of fuel supply limitations.

The opportunity cost is the shadow price corresponding to the binding environmental or operational limit. The shadow price is defined as the marginal decrease in the net revenue due to a one hour equivalent decrease in the binding environmental or operation limit.

The opportunity cost adder is calculated as the average of the three opportunity cost values corresponding to the three sets of forward LMPs and forward delivered fuel prices.

### **12.7.7 Market Participant Requirements**

Market Participants must make available to the MMU the following information:

- Permits describing environmental limitations imposed on the generator;
- OEM documentation or insurance carrier documentation for physical equipment limitations;
- Operating parameters necessary for the calculation (Economic Minimum, Economic Maximum, heat rate curve, minimum downtime, maximum weekly starts, maximum daily starts, emission rates, start-up emission rates, fuel consumption rates during start-up);
- Fuel price information;
- Emission levels for the previous 12 month period in the case of environmental limitations;
- Hours of operation and number of starts for generators subject to operational limitations.

Information that is currently included in the Cost Offer Assumptions (COA) or the Fuel Policy as part of the Member Information Reporting Application (MIRA) does not need to be resubmitted.
